24 **Abstract**

25 Today, there is no effective non-thermal method to inactivate unwanted bacterial spores in
26 foods. High-Pressure (HP) process has been shown to act synergistically with moderate
27 heating and the bacteriocin nisin to inactivate spores but the mechanisms have not been
28 elucidated. The purpose of the present work was to investigate in depth the synergy of HP and
29 nisin on various foodborne spore species and to bring new elements of understandings.

30 For this purpose, spores of *Bacillus pumilus*, *B. sporothermodurans*, *B. licheniformis*, *B.*
31 *weihenstephanensis*, and *Clostridium* sp. were suspended in MES buffer, in skim milk or in a
32 liquid medium simulating cooked ham brine and treated by HP at 500 MPa for 10 min at
33 50 °C or 20 °C. Nisin (20 or 50 IU/mL) was added at three different points during treatment:
34 during HP, during and or in the plating medium of enumeration. In the latter two cases, a high
35 synergy was observed with the inhibition of the spores of *Bacillus* spp.. The evaluation of the
36 germinated fraction of *Bacillus* spp. spores after HP revealed that this synergy was likely due
37 to the action of nisin on HP-sensitized spores, rather than on HP-germinated spores. Thus, the
38 combination of nisin and HP can lead to *Bacillus* spp. spore inhibition at 20°C. And Nisin can
39 act on HP-treated spores, even if they are not germinated.

40 This paper provides new information about the inhibition of spores by the combination of HP
41 and nisin. The high synergy observed at low temperature has not been reported yet and could
42 allow food preservation without the use of any thermal process.

43 **Keywords**

44 *Bacillus*, *Clostridium*, psychrotrophic, highly-heat-resistant, germination

45 **1. Introduction**

46 When exposed to unfavorable environmental conditions, several bacterial species, mostly
47 *Bacillus* and *Clostridia*, can enter a metabolically dormant state by forming endospores.
48 Endospores (here after called “spores”) have exceptional resistance properties against high
49 temperatures, radiation, desiccation, pressure and toxic chemicals. They can survive under
50 starvation for years before germinating and forming vegetative cells again.

51 Spore-forming bacteria play an important role in food spoilage and foodborne disease (Wells-
52 Bennik et al. 2016). High-heat treatments, such as sterilization or Ultra-High-Temperature
53 (UHT) treatments, are needed to inactivate spores in food products. Such treatments are
54 usually effective to reduce spores to sufficiently low numbers; however, various species of
55 sporeformers, such as *Bacillus sporothermodurans*, are able to survive commercial wet heat
56 sterilization (André et al. 2013; Huemer et al. 1998). In addition, non-sterilized and low-acid
57 food, such as refrigerated ready-to-eat-food, can be contaminated by bacterial spores, namely,
58 from psychrotrophic species such as non-proteolytic *Clostridium botulinum* species (Mills et
59 al. 2014). As a consequence, preservative ingredients are often required to ensure their safety.

60 The high-pressure (HP) process is used worldwide as an alternative to heat pasteurization or
61 as an additional decontamination step in packaged food products. However, similar to many
62 inactivation technologies, HP alone is not effective on bacterial spore destruction (Black et
63 al., 2007a). If HP at a temperature lower than 50 °C can hardly inactivate spores, it has long
64 been known that HP initiates germination of the spores of *Bacillus sp.* and *Clostridium sp.*
65 when applied between 200 - 400 MPa (Doona et al. 2016; Reineke et al. 2013).

66

67 HP has also been shown to act synergistically with nisin to inactivate spore-forming bacteria
68 of various species. In the abundant literature on the subject, the experimental conditions tested

69 are very different from one study to another. The tested species are different; the nisin
70 concentrations are not always expressed in the same units and vary from 0.2 to more than
71 2000 IU / mL. Finally, the contact between spores and nisin is not performed under the same
72 conditions. In most studies reporting a synergy, nisin is added at concentrations ranging from
73 120 to 500 IU/mL to the spore suspension before a combined heat and HP treatment (Aouadhi
74 et al. 2013; Black et al., 2008; Gao et al. 2011; Kalchayanand et al., 2003; Sokolowska et al.,
75 2012). Rare studies were interesting in adding nisin in the spore recovery medium after HP.
76 Lopez-Pedemonte et al. (2003) show that adding nisin at 15600 UI/mL in two-pressure-cycle-
77 HP treated cheeses increased the inactivation of *Bacillus cereus* and inhibited the regrowth
78 during 15 days. And Roberts and Hoover (1996) found that an HP treatment (400 MPa, 70 °C
79 and low pH) renders spores of *Bacillus coagulans* more sensitive to nisin present in the
80 recovery medium.

81 The objective of the present work was to investigate the effect of the combination of HP and
82 nisin on the inactivation of relevant food pathogenic and spoilage spore species in nutrient
83 media to clarify the conditions allowing the synergy. *Bacillus sporothermodurans*, *B.*
84 *pumilus*, and *B. licheniformis* were chosen for their high resistance to temperature and their
85 frequent implication in UHT and raw milk spoilage (Aouadhi et al. 2014; Klijn et al. 1997;
86 Kmiha et al. 2017). *Clostridium* sp. and *B. weihenstephanensis* were chosen regarding their
87 potential pathogenicity and ability to contaminate meat products and for growing at
88 refrigerated temperatures (Mazuet et al. 2015; Thorsen et al. 2006).

89 For this purpose, low nisin concentrations (≤ 50 IU/mL), which highlight the synergy, were
90 added to the spore suspensions during HP treatments at 20 and 50 °C and/or after treatment in
91 the recovery medium to identify when inhibition occurs. Furthermore, without this being
92 proved, it is generally admitted that HP germination is the underlying mechanism of the

93 synergy between nisin and HP. Thus, our aim was also to clarify whether spore germination is
94 necessary for the action of nisin on HP treated spores.

95 **2. Material and methods**

96 **2.1 Bacterial strains, growth and sporulation conditions**

97 *Bacillus weihenstephanensis* KBAB4 (provided by the Institut National de Recherche
98 Agronomique, Unité SQPOV, Avignon, France), *Bacillus licheniformis*, *Bacillus pumilus*
99 (both isolated from UHT Tunisian milk), *Bacillus sporothermodurans* (isolated from raw
100 Tunisian milk) (Kmiha et al. 2017) and *Clostridium* sp. BAFF C3DSM 1985 were used as
101 target strains in this study. As reported on the DSMZ website, this strain is, based on a partial
102 16S rDNA sequence, closely related to *Clostridium botulinum* type E, strain ATCC 23387
103 (Curators of the DSMZ n.d.).

104 Table 1 presents the conditions applied to produce the bacterial spores used in this study.

105 For *Bacillus* species, cultures were obtained by inoculating 2-3 fresh colonies into 50 mL of
106 nutrient broth. After incubation (see Table 1), 0.4 mL of the culture was spread on sporulation
107 Petri dishes (\varnothing : 145 mm; h: 20 mm).

108 Sporulation was monitored by phase contrast microscopy and spores were harvested when
109 more than 95% of phase bright spores were observed. Spores were harvested by flooding the
110 agar plates with cold sterile distilled water and scraping the agar surface with a sterile cell
111 spreader. Spore suspensions were centrifuged (3600 g, 15 min, 4 °C) and spores were
112 suspended in 0.2 μ m filtrated 70% ethanol (filter: cellulose acetate, Sartorius, France; ethanol:
113 Elvetec, France) for 1 h to inactivate vegetative cells (Koransky et al. 1978). Spores were then
114 washed three times by successive centrifugation (3600 g, 15 min, 4 °C) and suspension in
115 sterile distilled water at 4 °C. Spores were enumerated by CFU determination on their

116 respective enumeration media (EM). The concentration of the final spore suspensions was
117 standardized at 10^8 CFU/mL. Suspensions were stored at 4 °C for a maximum of one month.
118 For *Clostridium* sp., a subculture was obtained by adding 0.1 mL of stock cultures previously
119 stored at -80 °C to 9 mL of LYBHI (Table 1) in an anaerobic Hungate tube incubated for 24 h
120 at 30 °C. A culture was obtained by diluting 0.5 mL of subculture into 10 mL of fresh LYBHI
121 in an anaerobic Hungate tube. After incubation, 0.2 mL of this culture was inoculated into
122 sporulation Petri dishes (Table 1) for sporulation. After one month at 30 °C under anaerobic
123 conditions, the spores were harvested, purified and enumerated as previously described for
124 *Bacillus* spp. strains. The concentration of the final spore suspensions was standardized at 10^7
125 CFU/mL. Suspensions were stored at 4 °C and stored for up to one month.

126

127 **2.2 Effect of nisin on spore cultivability**

128 Nisin stock solution in 0.02 mol/L HCl was prepared from nisin powder (10^6 IU/g, Sigma-
129 Aldrich, France) and sterilized by 0.2 µm filtration (cellulose acetate, Sartorius, France).
130 Nisin stock solution was stored at 4 °C for a maximum of one week until use. The nisin level
131 of the stock solution was confirmed by a plate diffusion assay using *Micrococcus flavus* DSM
132 1790, as described by Tramer and Fowler (Tramer and Fowler 1964). Following a protocol
133 adapted from Stewart et al. (2000), nisin stock solution was added to tempered agar
134 enumeration medium (Table 1) to achieve final concentrations ranging from 0 IU/mL to 200
135 IU/mL (Stewart et al., 2000). Spore suspensions were serially diluted and plated on their
136 respective enumeration media supplemented with nisin (Table 1). Plates were incubated for
137 48 h (temperatures indicated in Table 1), and colonies were counted. The spore cultivability
138 was plotted against the nisin concentration, and concentrations inducing less than -1.5 logs
139 (CFU/mL) spore count reduction were selected for treatment combining HP and nisin.

140 Therefore, 50 IU/mL was chosen as the nisin concentration for all the *Bacillus* spp., and 20
141 IU/mL was chosen for *Clostridium* sp.

142 **2.3 HP treatments in buffer and measurement of germination**

143 HP tests were performed in a 700 MPa vessel (Top Industrie, France) with a double-walled
144 metal pressure chamber of 20 cm³ (working temperature: -20 °C / 90 °C). Water was used as
145 the pressure-transmission fluid. The internal temperature of the pressure chamber was
146 maintained by a water bath (Minisat 240, Huber, Germany) connected to the double wall of
147 the pressure chamber and monitored by a Pt100 thermocouple (Omega, USA). The
148 temperature of the water bath was set to limit the adiabatic heating to +5 °C above the desired
149 temperature set point. The pressure and temperature during HP treatment were recorded using
150 the instruNet World (iW) software. The compression rate was 3 MPa/s and the decompression
151 was nearly instantaneous (< 3 sec).

152 Samples were prepared by a 90% dilution of the initial spore suspensions into 0.11 mol/L 2-
153 (N-morpholino) ethane sulfonic acid (MES) buffer at pH 6.1 (Sigma Aldrich, France) to reach
154 a final concentration of approximately 10⁷ CFU/mL for *Bacillus* spp. and 10⁶ CFU/mL for
155 *Clostridium* sp.. MES buffer was chosen because its pH varies only slightly with temperature
156 and pressure ($\Delta pK_a / ^\circ C = -0.011$; pH varies from 5.5 to 6.5 between 10 and 1000 MPa at
157 25°C) (Bruins et al. 2007). Then, 0.5 mL of each spore suspensions in MES was heat-sealed
158 into polyethylene pouches (polyethylene transfer pipet, Dominique Dutscher). For each strain,
159 zero-time samples were taken to determine the initial concentration of the spores before
160 treatment.

161 Pouches were placed in the HP vessel 5 min before treatment to let the temperature
162 equilibrate. Samples were treated at 500 MPa for 10 min, at 20 °C or 50 °C and immediately
163 immersed in iced water.

164 After treatment, samples were divided into two equal volumes, one of which was treated at 80
165 °C for 10 min in a water bath to inactivate germinated spores. The two volumes were then
166 serially diluted and 100 µL of each dilution were plated on the sample enumeration media
167 (Table 1). The fraction of spores induced in germination by HP was calculated as the
168 difference between the logarithmic counts of in pressure- and heat-treated (N_{HPT}) and
169 pressure-treated (N_{HP}) portions of the samples ($\log_{10}(N_{HPT}) - \log_{10}(N_{HP})$).

170

171 **2.4 HP treatment with nisin**

172 Immediately before HP treatment, spore suspensions were diluted to approximately 10^7
173 CFU/mL for *Bacillus* spp. and 10^6 CFU/mL for *Clostridium* sp. in MES buffer supplemented
174 or not supplemented with nisin at 50 UI/mL or 20 UI/mL for *Bacillus* spp. and *Clostridium*
175 sp. respectively. Immediately after HP treatment, spore suspensions were centrifuged at
176 11200 g for 5 min at 4 °C, and spores were re-suspended in PBS (phosphate buffered saline,
177 Sigma-Aldrich, France). Spores were then plated both on their respective EM (Table 1) and
178 on EM supplemented with nisin at 20 or 50 IU/mL for *Clostridium* sp. and *Bacillus* spp.
179 respectively. After 48 h of incubation (see temperatures in Table 1), colonies were counted.
180 As a control for the effect of nisin alone, non-HP-treated samples were plated on EM + nisin.

181 **2.5 HP treatments in nutrient media**

182 UHT skim milk (Lactel, Lactalis, France) was used as a nutrient medium for the HP treatment
183 of *B. pumilus*, *B. sporothermodurans* and *B. licheniformis* strains.

184 For *B. weihenstephanensis* and *Clostridium* sp., a liquid medium was formulated to suit the
185 physicochemical properties of cooked ham brine (pH, a_w , sugars and salt contents). The
186 composition of this Medium Modelling Ham (MMH) was adapted from the composition of
187 typical organic ham brine. The MMH is composed of 17.6 g/L of sodium chloride (Sigma

188 Aldrich, France); 10 g/L of peptone from porcine heart (Sigma-Aldrich, France); 5 g/L of
189 autolytic yeast extract (Biokar, France); 2.3 g/L of D-lactose monohydrate (Sigma-Aldrich,
190 France); 0.7 g/L of Sucrose (Sigma-Aldrich, France); and 0.11 mol/L MES buffer *qs* 1 L
191 (Sigma-Aldrich). The pH was adjusted to 6.1 before autoclaving.

192 Nitrites, which are usually added as preservatives in ham brine, were omitted to focus only on
193 the effects of HP and nisin on the spores.

194 For HP treatment without nisin, spores were suspended in their respective nutrient media
195 (MMH for *B. weihenstephanensis* and *Clostridium* sp. and skim milk for *B. pumilus*, *B.*
196 *sporofermodurans* and *B. licheniformis*), treated by HP at 500 MPa at 50 °C or 20 °C for 10
197 min and plated on EM for CFU determination.

198 In the case of HP treatment with nisin, the bacteriocin was present during HP treatment and
199 into the recovery medium..

200

201 **2.6 Statistical analysis**

202 All experiments were independently performed 3 times. The effect of the factors on spore
203 inactivation after HP treatment was evaluated for each strain by analysis of variance
204 (ANOVA) using R software (R development core team, 2008). Significance was considered
205 to be when the p-value was equal to or less than 0.05. In this case, a Tukey's HSD (Honest
206 Significant Difference) test was performed to observe significant differences among the
207 conditions.

208 In the case of HP treatment in combination with nisin, the sum of the independent effects of
209 HP and nisin was compared with the effect of the treatment combining HP and nisin. When
210 the effect of the combined treatments was significantly higher than the addition of the two
211 independent effects, a synergy was attained.

212 A Student's t-test using a 5% level of significance ($p < 0.05$) was used to detect differences
213 between the sum of the HP-germinated and inactivated spore fractions and the total
214 inactivation provided by the application of nisin during and after HP.

215 **3. Results and Discussion**

216 **3.1 Effect of HP and nisin on spore inactivation in the buffer**

217 Spores were suspended in MES buffer and treated with nisin. Nisin concentrations used were
218 50 IU/mL for *Bacillus* spp. and 20 IU/mL for *Clostridium* sp.

219 Nisin was added at different stages of treatment, creating two groups of samples:

- 220 - Nisin present only during HP (plating on EM without nisin)
- 221 - Nisin present during HP and added into the plating medium at the same concentration.

222 The results obtained are shown in Fig. 1. The effect of nisin alone on the spores (striped bars)
223 represents the inhibition of spores by only plating on the EM + nisin. As expected, nisin at 50
224 IU/mL and 20 IU/mL induced approximately 1 log inhibition of *Bacillus* spp. and *Clostridium*
225 sp. spores respectively (that is what the nisin concentration was determined for). Regarding
226 the effect of HP alone, it can be noticed that pressure resistance of spores is strongly related to
227 the temperature of the treatment. While spores treated at 20 °C did not show any significant
228 inactivation (<1 log for all the strains), the viability of the spores of *B. weihenstephanensis*
229 and *B. pumilus* processed at 50 °C was strongly affected (approx. 4 log inactivation for the
230 two strains).

231 Spores of psychrotrophic species, such as *Clostridium* sp. and *Bacillus weihenstephanensis*
232 are poorly heat-resistant (Garcia et al., 2010; Juneja et al., 1995) while *Bacillus pumilus*,
233 *Bacillus licheniformis* and *Bacillus sporothermodurans* are highly heat-resistant spores
234 isolated from UHT milk (Kmiha et al., 2017). Our results confirm the absence of a link

235 between thermo- and baroresistance according to what has been reported in the rare literature
236 on the subject (Margosch et al. 2004; Nakayama et al. 1996). Three groups of spore species
237 clearly appear according to their baroresistance at a temperature ≤ 50 °C, in order of
238 increasing baroresistance: *B. weihenstephanensis*; *B. pumilus* > *B. licheniformis*; *B.*
239 *sporotheodurans* > *Clostridium* sp. It is well known that inactivation by HP beyond 400
240 MPa was related to the germination induction during HP treatment and the subsequent
241 resistance loss. At this pressure level, this induction was thought to be driven through spoVA
242 channel activation and Ca-DPA release in *B. subtilis* (Reineke et al. 2013). The *B. subtilis*
243 spoVA proteins are composed of 7 subunits, including the SpoVAC subunit, which has
244 recently been identified as a mechanical stress sensitive channel for DPA release (Velásquez
245 et al. 2014). *B. pumilus* and *B. licheniformis* also have genes from the same spoVA subunits
246 as *B. subtilis* (Paredes-Sabja et al. 2011), but it is not known for the other two species of
247 *Bacillus* studied here. Moreover, the lytic enzymes of the cortex can be denatured by HP at
248 500 MPa, which consequently inhibits the second stage of germination (Wuytack et al. 1998).
249 Thus, baroresistance differences could be attributed to varying sensitivities of DPA spoVA
250 channels and lytic enzymes of the cortex in different *Bacillus* species. Regarding *Clostridium*
251 spores, there are important differences in the germination mechanisms of *Bacillus* spores and
252 certain *Clostridium* species. HP has recently been shown to cause the release of DPA by some
253 *Clostridium* species (Doona et al. 2016). However, our results show that the effect of HP up to
254 600 MPa (results not shown) at the moderate temperature on the inactivation of *Clostridium*
255 sp. remains low. This corresponds to what is already reported in the literature on *C. botulinum*
256 type E (Reddy et al. 1999).

257 When nisin was present during HP, a slightly significant increase in spore inactivation was
258 found at 20 °C and 50 °C for *B. sporotheodurans* and *B. licheniformis* ($p < 0.01$). In
259 comparison with the effects of HP alone, the addition of nisin during HP provided a 1 log

260 supplementary inactivation for both strains. Nisin addition during HP also provided a
261 significant and synergistic increase in the inactivation of *B. pumilus* only at 20 °C
262 (inactivation: 2.5 log; $p < 0.001$). In contrast, nisin addition during HP did not significantly
263 improve *B. weihenstephanensis* and *Clostridium sp.* inactivation, regardless of the
264 temperature. The same applied for *B. pumilus* at 50 °C. However, the presence of nisin during
265 HP and into the plating medium induced a significant, synergistic effect on the reduction of
266 the outgrowth of *B. sporothermodurans*, *B. licheniformis* and *B. weihenstephanensis*, both at
267 20 °C and 50 °C ($p < 0.001$). For *Clostridium sp.* treated at 50 °C and *B. pumilus* treated at 20
268 °C, a significant further reduction in spore outgrowth was provided by nisin addition during
269 HP and into the plating medium ($p < 0.01$), resulting in the addition of the independent effects
270 of HP and nisin.

271 **3.2 Effect of HP and nisin on spore inactivation in nutrient media**

272 *B. licheniformis*, *B. pumilus*, and *B. sporothermodurans* in suspension in skim milk and *B.*
273 *weihenstephanensis*, and *Clostridium sp.* in suspension in MMH were treated by HP at 500
274 MPa for 10 min at 20 °C or 50 °C. Nisin was added to the spore suspensions just before HP
275 treatment to reach 20 IU/mL for *Clostridium sp.* and 50 IU/mL for *Bacillus spp.* to simulate
276 the presence of nisin in HP-treated food products, nisin was also added into the plating
277 medium. Results are shown in Fig. 2.

278 First, regarding the effect of HP alone, we noticed that inactivation was reduced when spores
279 were treated in nutrient media, in comparison with the inactivation obtained after HP
280 treatment in MES buffer. This reduction was significant for *B. pumilus* and *B.*
281 *weihenstephanensis* at 50 °C for which the inactivation was reduced by 2.5 log and 2 log
282 respectively. The protective effect of MMH on *B. weihenstephanensis* could be due to the
283 presence of sodium chloride and sugars, inducing lower water activity (MMH a_w : 0.97)

284 (Daryaei et al. 2016). A slight protective effect was also noticed for spores treated in milk. A
285 possible explanation for this may be the natural baroprotective effect of milk, due to its high
286 content in calcium and magnesium (Black et al. 2007b; Hauben et al. 1998).

287 Second, the combination of HP and nisin gave similar results in nutrient media and in buffer.
288 Indeed, a significant, synergistic effect was obvious for all the strains when nisin was present
289 during HP and in the plating medium ($p < 0.001$), except for *Clostridium* sp. However, the
290 outgrowth inhibition of *Bacillus* spp. was lower than after HP treatments in buffer.
291 Particularly, the inhibition of *B. licheniformis* at 20 °C was significantly reduced from -5 log
292 in buffer to -3.5 log in milk ($p < 0.01$). This could be due to nisin adsorption on milk
293 proteins, resulting in a decrease in its antimicrobial activity (Lakamraju et al. 1996).

294 Nevertheless, a high synergy was found in both buffer and nutrient media for *B.*
295 *sporotheodurans*, *B. pumilus*, *B. licheniformis* and *B. weihenstephanensis*, leading to a
296 reduction of spore outgrowth of over 4 logs for all the *Bacillus* spp. strains.

297 Recovery of *Bacillus* and *Clostridium* spore growth was inhibited in the presence of nisin
298 (Egan et al. 2016; Hofstetter et al. 2013). The inhibitory effect of nisin occurred rapidly (<5
299 minutes) after the initiation of germination. It appeared that nisin prevented spores from
300 becoming metabolically active by disrupting the establishment of their membrane potential
301 (Gut et al. 2008). Nisin binds to lipid II for both spores and vegetative cells, but for spores,
302 this is not sufficient to induce membrane pore formation and thus inhibits growth recovery
303 (Gut et al. 2011). The formation of pores could also be due to the binding of nisin to the thiol
304 groups of membrane proteins which become accessible only at the time of spore germination
305 (Morris et al. 1984). It is thus commonly admitted that the synergy between HP and nisin is
306 due to the action of nisin on HP-germinated spores which appeared more sensitive to nisin
307 than spore germinated in the growth medium. Some authors also hypothesized HP-induced

308 physical damages to the spore outer layers (coat and cortex) allow nisin molecules access to
309 their site of action without germination (Aouadhi et al. 2013). We thus measured the number
310 of HP-germinated spores to clarify whether spore germination is a necessary condition for the
311 action of nisin on HP treated spores.

312 **3.3 Effect of HP on spore inactivation and germination induction**

313 We hypothesized that spores, whose germination was initiated by HP, became sensitive to
314 nisin. We thus measured the HP-induced germination rate of the spores. Spores of *B.*
315 *licheniformis*, *B. pumilus*, *B. sporothermodurans*, and *B. weihenstephanensis* in suspension in
316 MES buffer were treated by HP at 500 MPa for 10 min at 50 °C or 20 °C. Spores induced in
317 germination (at least first stage) after HP were immediately inactivated at 80 °C for 10 min.
318 Fig. 3 presents the HP-inactivated spore fraction (dark grey bars), the HP-germinated spores
319 fraction (light grey bars) and the total spore inhibition provided by the addition of nisin during
320 HP and into the plating medium (black bars). The cumulated inactivation (dark and light grey
321 bars) represent the inactivation obtained after pressure and temperature treatments.

322 First, the major phenomenon observed after HP at 50 °C is the spore HP inactivation, while
323 the germination without HP-inactivation represented less than 1 log for all the strains. In
324 contrast, after HP treatment at 20°C, a large proportion of spores was germinated and not
325 inactivated by HP.

326 Second, the cumulative HP-inactivated and germinated spore fraction are significantly lower
327 than the total inhibition provided by the treatment combining HP and nisin for all the
328 treatments, except *B. pumilus* and *B. licheniformis* at 50 °C ($p < 0.05$). For these two
329 treatments, the spores inhibited by the combination of HP and nisin were equivalent those
330 inactivated by a combination of HP and thermal treatment.

331 With the hypothesis that heat treatment after HP (80°C, 10 min.) inactivates all the HP
332 induced-germinated spores, i.e. spore having released DPA after HP, the results presented in
333 Fig. 3 clearly indicate that nisin sensitization does not simply come from spores induced in
334 germination by HP. However, our results do not allow concluding if the spores are only
335 reversibly inhibited by the combination of HP and nisin or if they are irreversibly inactivated
336 in the presence of nisin in their growth medium.
337 Nevertheless, HP induced a modification or an alteration of the spores which sensitized spores
338 to nisin without necessarily inducing germination.
339 HP could target spore coat or cortex. Rare studies show that spores with a damaged cortex are
340 more sensitive to nisin (Delves-Broughton et al. 1996; Rao et al. 2016).
341 Functionally, the spore coat constitutes an initial barrier to large molecules, such as
342 peptidoglycan-lytic enzymes, which would otherwise have access to the spore cortex (Leggett
343 2012). The spore coat has also been identified as a critical resistance layer against many
344 chemicals, especially oxidizing agents, such as nitrogen peroxide, ozone, chlorine and
345 hypochlorite. In contrast, smaller molecules, such as the spore germinants, must presumably
346 pass through this barrier. Nisin is a cationic peptide with a molar weight of 3300 Da, and its
347 potential interaction with the spore coat is unknown.
348 Finally, the inhibition of spores by nisin after HP could be due to the modification of the
349 properties of some inner membrane proteins, resulting in a better binding of nisin to
350 sulfhydryl groups. Indeed, HP acts generally by promoting the unfolded form of the proteins,
351 which are less voluminous than the native form. Pressures between 100 MPa and 500 MPa
352 have been shown to increase the number and reactivity of sulfhydryl groups by unfolding the
353 protein structure and exposing the interior sulfhydryl groups (Funtenerger et al. 1997; Zhang
354 et al. 2015).

355 **4. Conclusion**

356 In conclusion, this work reports an important sporostatic effect of combining an HP treatment
357 at 500 MPa and the addition of nisin into the recovery medium for several food-borne
358 *Bacillus* species. The inhibition is significant even if the HP treatment is carried out at 20 °C
359 and with a concentration of nisin as lower as 50 IU/ml while the regulatory concentration in
360 Europe is 120 to 500 IU/mL. Furthermore, we demonstrated that the inhibition of growth
361 shown by the combination of HP and nisin does not need that spores are induced in
362 germination by HP. The underlying mechanism needs further investigation, which is currently
363 underway with *Bacillus subtilis* to bring new elements of understanding
